

# Inference in regression

Brian Caffo, Jeff Leek and Roger Peng Johns Hopkins Bloomberg School of Public Health

### Recall our model and fitted values

· Consider the model

$$Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$$

- $\cdot \in \sim N(0, \sigma^2)$ .
- · We assume that the true model is known.
- · We assume that you've seen confidence intervals and hypothesis tests before.
- $. \quad \hat{\beta}_0 = \bar{Y} \hat{\beta}_1 \bar{X}$
- $\hat{\beta}_1 = Cor(Y, X) \frac{Sd(Y)}{Sd(X)}$ .

#### **Review**

- . Statistics like  $\frac{\hat{\theta}-\theta}{\hat{\sigma}_{\hat{\theta}}}$  often have the following properties.
  - 1. Is normally distributed and has a finite sample Student's T distribution if the estimated variance is replaced with a sample estimate (under normality assumptions).
  - 2. Can be used to test  $H_0: \theta = \theta_0$  versus  $H_a: \theta >, <, \neq \theta_0$ .
  - 3. Can be used to create a confidence interval for  $\theta$  via  $\hat{\theta} \pm Q_{1-\alpha/2} \, \hat{\sigma}_{\hat{\theta}}$  where  $Q_{1-\alpha/2}$  is the relevant quantile from either a normal or T distribution.
- · In the case of regression with iid sampling assumptions and normal errors, our inferences will follow very similarly to what you saw in your inference class.
- · We won't cover asymptotics for regression analysis, but suffice it to say that under assumptions on the ways in which the X values are collected, the iid sampling model, and mean model, the normal results hold to create intervals and confidence intervals

## Standard errors (conditioned on X)

$$\begin{split} Var(\hat{\beta}_{1}) &= Var\Bigg(\frac{\sum_{i=1}^{n}(Y_{i} - \bar{Y})(X_{i} - \bar{X})}{\sum_{i=1}^{n}(X_{i} - \bar{X})^{2}}\Bigg) \\ &= \frac{Var\Big(\sum_{i=1}^{n}Y_{i}(X_{i} - \bar{X})^{2}\Big)}{\Big(\sum_{i=1}^{n}(X_{i} - \bar{X})^{2}\Big)^{2}} \\ &= \frac{\sum_{i=1}^{n}\sigma^{2}(X_{i} - \bar{X})^{2}}{\Big(\sum_{i=1}^{n}(X_{i} - \bar{X})^{2}\Big)^{2}} \\ &= \frac{\sigma^{2}}{\sum_{i=1}^{n}(X_{i} - \bar{X})^{2}} \end{split}$$

### Results

- $\cdot \ \sigma_{\hat{\beta}_1}^2 = Var(\hat{\beta}_1) = \sigma^2/\textstyle\sum_{i=1}^n (X_i \bar{X})^2$
- $\sigma_{\hat{\beta}_0}^2 = \operatorname{Var}(\hat{\beta}_0) = \left(\frac{1}{n} + \frac{\bar{X}^2}{\sum_{i=1}^n (X_i \bar{X})^2}\right) \sigma^2$
- · In practice,  $\sigma$  is replaced by its estimate.
- · It's probably not surprising that under iid Gaussian errors

$$\frac{\hat{\beta}_j - \beta_j}{\hat{\sigma}_{\hat{\beta}_i}}$$

follows a t distribution with n-2 degrees of freedom and a normal distribution for large n.

· This can be used to create confidence intervals and perform hypothesis tests.

### Example diamond data set

```
library(UsingR); data(diamond)
y <- diamond$price; x <- diamond$carat; n <- length(y)
beta1 <- cor(y, x) * sd(y) / sd(x)
beta0 <- mean(y) - beta1 * mean(x)
e <- y - beta0 - beta1 * x
sigma <- sqrt(sum(e^2) / (n-2))
ssx <- sum((x - mean(x))^2)
seBeta0 <- (1 / n + mean(x) ^ 2 / ssx) ^ .5 * sigma
seBeta1 <- sigma / sqrt(ssx)
tBeta0 <- beta0 / seBeta0; tBeta1 <- beta1 / seBeta1
pBeta0 <- 2 * pt(abs(tBeta0), df = n - 2, lower.tail = FALSE)
pBeta1 <- 2 * pt(abs(tBeta1), df = n - 2, lower.tail = FALSE)
coefTable <- rbind(c(beta0, seBeta0, tBeta0, pBeta0), c(beta1, seBeta1, tBeta1, pBeta1))
colnames(coefTable) <- c("Estimate", "Std. Error", "t value", "P(>|t|)")
rownames(coefTable) <- c("(Intercept)", "x")</pre>
```

### **Example continued**

coefTable

```
Estimate Std. Error t value P(>|t|)
(Intercept) -259.6 17.32 -14.99 2.523e-19
x 3721.0 81.79 45.50 6.751e-40
```

```
fit <- lm(y \sim x);
summary(fit)$coefficients
```

```
Estimate Std. Error t value Pr(>|t|)
(Intercept) -259.6 17.32 -14.99 2.523e-19
x 3721.0 81.79 45.50 6.751e-40
```

### Getting a confidence interval

```
sumCoef <- summary(fit) \\ sumCoef[1,1] + c(-1, 1) * qt(.975, df = fit\\ \\ sumCoef[1, 2]
```

```
[1] -294.5 -224.8
```

```
sumCoef[2,1] + c(-1, 1) * qt(.975, df = fit$df) * sumCoef[2, 2]
```

```
[1] 3556 3886
```

With 95% confidence, we estimate that a 0.1 carat increase in diamond size results in a 355.6 to 388.6 increase in price in (Singapore) dollars.

### **Prediction of outcomes**

- $\cdot$  Consider predicting Y at a value of X
  - Predicting the price of a diamond given the carat
  - Predicting the height of a child given the height of the parents
- · The obvious estimate for prediction at point  $x_0$  is

$$\hat{\beta}_0 + \hat{\beta}_1 x_0$$

- · A standard error is needed to create a prediction interval.
- · There's a distinction between intervals for the regression line at point  $x_0$  and the prediction of what a y would be at point  $x_0$ .

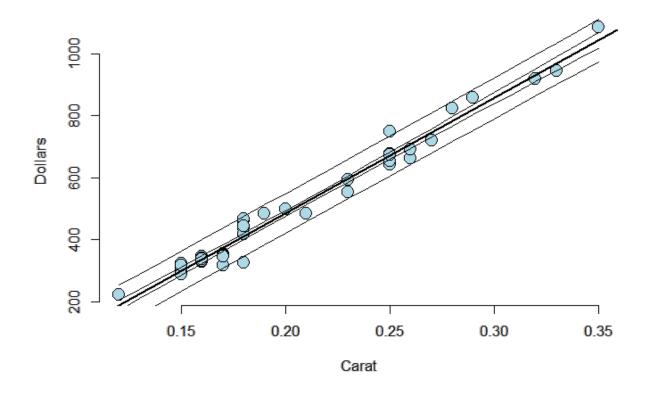

. Line at 
$$x_0$$
 se,  $\hat{\sigma}\sqrt{\frac{1}{n}+\frac{\left(x_0-\bar{X}\right)^2}{\sum_{i=1}^n(X_i-\bar{X})^2}}$ 

Prediction interval se at 
$$x_0$$
,  $\hat{\sigma}\sqrt{1+\frac{1}{n}+\frac{(x_0-\bar{X})^2}{\sum_{i=1}^n(X_i-\bar{X})^2}}$ 

### Plotting the prediction intervals

```
plot(x, y, frame=FALSE,xlab="Carat",ylab="Dollars",pch=21,col="black", bg="lightblue", cex=2)
abline(fit, lwd = 2)
xVals <- seq(min(x), max(x), by = .01)
yVals <- beta0 + beta1 * xVals
sel <- sigma * sqrt(1 / n + (xVals - mean(x))^2/ssx)
se2 <- sigma * sqrt(1 + 1 / n + (xVals - mean(x))^2/ssx)
lines(xVals, yVals + 2 * sel)
lines(xVals, yVals - 2 * se2)
lines(xVals, yVals - 2 * se2)</pre>
```

# Plotting the prediction intervals

#### **Discussion**

- · Both intervals have varying widths.
  - Least width at the mean of the Xs.
- · We are quite confident in the regression line, so that interval is very narrow.
  - If we knew  $\beta_0$  and  $\beta_1$  this interval would have zero width.
- · The prediction interval must incorporate the variabilibity in the data around the line.
  - Even if we knew  $\beta_0$  and  $\beta_1$  this interval would still have width.

#### In R

```
newdata <- data.frame(x = xVals)
pl <- predict(fit, newdata, interval = ("confidence"))
p2 <- predict(fit, newdata, interval = ("prediction"))
plot(x, y, frame=FALSE,xlab="Carat",ylab="Dollars",pch=21,col="black", bg="lightblue", cex=2)
abline(fit, lwd = 2)
lines(xVals, p1[,2]); lines(xVals, p1[,3])
lines(xVals, p2[,2]); lines(xVals, p2[,3])</pre>
```

# In R
